Abstract

We present a criterion for the global existence of Euler's multiplier for an integrable one-form taking into account the corresponding codim-1-foliation. In particular, the impact of inseparable leaves is considered. Here, we suppose that the foliation can be reduced to a graph. The properties of this graph are crucial for the global existence of the Euler's multiplier. As applications we investigate some special cases in which the graph turns out to look very simple.

1 Introduction

First order differential equations of the form

$$(1) \quad g(x, y)dx + h(x, y)dy = 0$$

sometimes can be transformed to exact differential equations and be solved by finding a so called integrating factor, i.e. some function $\lambda = \lambda(x, y) \neq 0$ such that there is some function $f = f(x, y)$ with the property

$$df = \lambda g dx + \lambda h dy.$$

In general, λ is supposed to vanish nowhere or, at least, in a set with no interior points (see [Ma94]). Then f is a first integral of equation (1) and the solutions are implicitly given by the equation $f(x, y) = \text{const}$. It is well known that, if $|g(x_0, y_0)| + |h(x_0, y_0)| > 0$, there are some neighbourhood U of (x_0, y_0) and nontrivial functions $\lambda, f : U \rightarrow \mathbb{R}$ as above.

In higher dimensions, the situation is more complicated. Let $r \in \mathbb{N}$, $r \geq 1$, and M be a real C^r manifold of dimension $n + 1$ and ω a C^r one-form on M . In this article we assume a manifold to be second countable, i.e. it has a countable topological base. This implies that it is paracompact, hence metrizable, and can be covered by a

*The author gratefully acknowledges support by the DFG-priority program "Global Methods in Complex Geometry".

countable number of charts. Now we ask for the existence of functions $f \in C^r(M, \mathbb{R})$, $\lambda \in C^{r-1}(M, \mathbb{R})$ such that $\lambda(x) \neq 0$ and

$$df = \lambda \omega$$

in M . In this case, λ is called Euler's multiplier. From $d(df) = 0$ follows immediately that

$$(2) \quad \omega \wedge d\omega = 0$$

is a necessary condition for the existence of such functions λ and f . In this case ω is called an integrable one-form. From Frobenius' theorem one can derive the *local* existence of λ and f in a neighbourhood of $p \in M$ if condition (2) is satisfied and $\omega(p) \neq 0$ (see e.g. [vWe]). But even if these conditions are satisfied everywhere in M and M is simply connected, global existence is, in general, not guaranteed. Consider the following example: Let $M = \mathbb{R}^3$, represented in cylinder coordinates $(\varrho, \phi, z) \in [0, \infty) \times [0, 2\pi) \times \mathbb{R}$, $w_\varrho := \varrho^2$,

$$w_\phi := \begin{cases} 0, & 0 \leq \varrho < \frac{1}{2} \\ 4(\varrho - \frac{1}{2})^2(\varrho - 1), & \frac{1}{2} \leq \varrho < 1 \\ \varrho - 1, & 1 \leq \varrho \end{cases} \quad w_z := \begin{cases} (\frac{1}{4} - \varrho^2)^2, & 0 \leq \varrho < \frac{1}{2} \\ 0, & \frac{1}{2} \leq \varrho \end{cases}$$

Figure 1:

$$\omega = w_\varrho d\varrho + w_\phi d\phi + w_z dz.$$

Obviously, ω vanishes nowhere and condition (2) is satisfied. But in any neighbourhood of $\{\varrho = 1\}$ Euler's multiplier cannot exist. Here, the geometry of those manifolds F , which are locally the level sets of a function f , forbid the existence of f and λ since they wind around the cylinder $\{\varrho = 1\}$ (see Fig. 1).

As we can deduce from this example, the geometry of these manifolds, which, in general, cannot be represented as submanifolds of M and which we will call *leaves*, has a decisive impact on the existence of λ and f .

The geometric term useful in this context is the codim-1-*foliation* induced by an integrable one-form (see §2). Obviously, in case of global existence of λ and f , all these leaves are closed subsets of M . Moreover, it turns out that the holonomy group (see §2) has to be trivial.

The first question is, whether those two conditions are sufficient for the global existence of Euler's multiplier. It turns out that this is only right if we additionally assume the leaves to be compact.

In general, to find a sufficient criterion for global existence, the differentiable structure of $M/\mathcal{F}$ is decisive. In $M/\mathcal{F}$, points of M lying on the same leaf are identified, in other words, $M/\mathcal{F}$ is the space of leaves. In general, the topology in $M/\mathcal{F}$ induced by the canonical projection $\pi : M \rightarrow M/\mathcal{F}$ is non-Hausdorff.

Note that for non-Hausdorff one-dimensional manifolds homeomorphic classes are different from diffeomorphic classes. So, if we only use topological properties of

$M/\mathcal{F}$ we cannot expect the full regularity of Euler's multiplier. In order to get a C^r multiplier we have to assume an additional property of $\mathcal{F}$ involving the differentiable structure. We call this property *regularly C^r* . The following example will shed some light on it:

By construction, any C^1 function f constant on the leaves would satisfy $f(x, y) = f(-x, -y^2)$, if $x < -1$ and $y < 0$. Hence $\frac{\partial f}{\partial y}(x, 0) = 0$, if $x < -1$. So $df(x, 0) = 0$. This prevents the existence of Euler's multiplier although the topological structure is admissible (compare § 5).

Figure 2: An irregular foliation on the slit plane

On the other hand, for Hausdorff one-dimensional manifolds there is no difference between homeomorphic classes and diffeomorphic classes. So, if we can prove $M/\mathcal{F} \cong \mathbb{R}$ in the topological sense, this will be enough to have Euler's multiplier.

In order to reduce $M/\mathcal{F}$ to its relevant topological properties, the terminology and the theory of graphs turn out to be appropriate means. More precisely, the structure of $M/\mathcal{F}$ will be displayed by a configuration of graphs. Here, the so called inseparable or non-Hausdorff leaves, i.e. leaves that cannot be separated in the topology of $M/\mathcal{F}$ play an important part. They determine essentially the structure of the graphs. The construction of the corresponding graphs is possible under some weak assumptions on the foliation $\mathcal{F}$ (cf. Def. 5.1). This leads us in a natural way to the concept of the graphical configuration induced by a codim-1-foliation (see §4), which finally yields an equivalent criterion for the global existence of Euler's multiplier.

In particular, we are able to give a 'classification' of obstructions for the global existence of Euler's multiplier, all but one can be expressed in terms of the topology of $M/\mathcal{F}$: (1.) non-regularity of $\mathcal{F}$, (2.) there is at least one non-closed point in $M/\mathcal{F}$, (3.) there is too much ramification in $M/\mathcal{F}$, (4.) there are other obstructions coming from the local topology of $M/\mathcal{F}$ or (5.) obstructions coming from the global topology of $M/\mathcal{F}$.

For an example for (3.) on $M = \mathbb{R}^2$ we refer to [CN, Ch. III, Notes] (found by Wazewski) or [H76].

The authors would like to express their gratitude to Wolf von Wahl for initiating this project.

2 Foliations and one-forms

2.1 Foliations

Let M be a real C^r manifold of dimension N . A maximal C^r atlas $\mathcal{F} = (U_\iota, \varphi_\iota)_{\iota \in \mathcal{J}}$ of M is called a *codim- k -foliation* if and only if

- (a) For each $\iota \in \mathcal{J}$ there exist open disks $X_\iota \in \mathbb{R}^{N-k}, Y_\iota \in \mathbb{R}^k$ such that

$$\varphi_\iota(U_\iota) = X_\iota \times Y_\iota,$$

(b) if $(U_{\iota_1}, \varphi_{\iota_1}), (U_{\iota_2}, \varphi_{\iota_2}) \in \mathcal{F}$ with $U_{\iota_1} \cap U_{\iota_2} \neq \emptyset$ then the mapping

$$\varphi_{\iota_2} \circ \varphi_{\iota_1}^{-1} : \varphi_{\iota_1}(U_{\iota_1} \cap U_{\iota_2}) \rightarrow \varphi_{\iota_2}(U_{\iota_1} \cap U_{\iota_2})$$

is of the form

$$(\varphi_{\iota_2} \circ \varphi_{\iota_1}^{-1})(x, y) = (\phi_{\iota_1 \iota_2}(x, y), \psi_{\iota_1 \iota_2}(y)).$$

The charts (U_ι, φ_ι) are called *foliation charts*. The leaves F of $\mathcal{F}$ are defined as follows: Fix any point $p \in U_{\iota_0} \subset M$. For any point $q \in M$ we will say $q \in F_p$ if and only if there exists a finite sequence $(\iota_\mu)_{\mu=0, \dots, m} \subset \mathcal{J}$ and $c_{\iota_0} \in Y_{\iota_0}, \dots, c_{\iota_m} \in Y_{\iota_m}$ such that

- (a) $U_{\iota_{\mu-1}} \cap U_{\iota_\mu} \neq \emptyset, \mu = 1, \dots, m,$
- (b) $\varphi_{\iota_{\mu-1}}^{-1}(X_{\iota_{\mu-1}} \times \{c_{\iota_{\mu-1}}\}) \cap \varphi_{\iota_\mu}^{-1}(X_{\iota_\mu} \times \{c_{\iota_\mu}\}) \neq \emptyset, \mu = 1, \dots, m,$
- (c) $p \in \varphi_{\iota_0}^{-1}(X_{\iota_0} \times \{c_{\iota_0}\}), q \in \varphi_{\iota_m}^{-1}(X_{\iota_m} \times \{c_{\iota_m}\})$

It is clear, that by $p \stackrel{\mathcal{F}}{\sim} q : \Longleftrightarrow q \in F_p$ an equivalence relation is defined. Any equivalence class $F = F_p = [p]_{\stackrel{\mathcal{F}}{\sim}}, p \in M$, will be called a leaf of $\mathcal{F}$.

The space of leaves is denoted by $M/\mathcal{F} := M/\stackrel{\mathcal{F}}{\sim}$, and $\pi : M \rightarrow M/\mathcal{F}, p \mapsto F_p$ is the canonical projection. In this article, we consider $M/\mathcal{F}$ as a topological space endowed with the topology induced by π . The projection π then becomes a continuous and open mapping.

In what follows, for any leaf F of $\mathcal{F}$ we will write $F \in M/\mathcal{F}$ if we consider F as a point in $M/\mathcal{F}$ and, deviating from the exact definition of the foliation, $F \in \mathcal{F}$ if F is considered as a subset of M .

At this occasion, we point out that, of course, the sets $\varphi_\iota^{-1}(X_\iota \times \{c\}), c \in Y_\iota$, are submanifolds of dimension $N-k$, but in general the leaves $F \in \mathcal{F}$ are not necessarily submanifolds; they are immersed manifolds. For this and other theorems in the theory of foliations used in this article we refer to [CN].

For any subset $U \subset M$ we define the *saturation* of U with respect to $\mathcal{F}$ by $\text{sat}(U) := \pi^{-1}(\pi(U))$. Any subset $U \subset M$ is called *saturated* (with respect to $\mathcal{F}$) if and only if $\text{sat}(U) = U$, i.e., for each $p \in U$ holds $F_p \subset U$.

We call the foliation *transversely orientable*, if the normal bundle given by $N_{\mathcal{F},x} := T_x M / T_x F_x$ is orientable. The transversely orientable codim-1-foliations are exactly those given by integrable one-forms.

2.2 The holonomy group

We now give a short sketch of the construction of holonomy. Fix a leaf F and a point $p \in F$. Now consider a closed path $\gamma : [0; 2\pi] \rightarrow F$ with $\gamma(0) = \gamma(2\pi) = p$. Now, if we choose a local transversal T through p and cover $\gamma([0; 2\pi])$ by a finite number of foliation charts $(U_\iota, \varphi_\iota)_{\iota=1, \dots, k}$, we can choose points $p_i \in \gamma([0; 2\pi])$ and local transversals T_i through p_i such that $T_i \cup T_{i+1} \subset U_{\iota_i}$ for a $\iota_i \in \{1, \dots, k\}$. By going into the foliation charts we are now able to choose a path $\gamma_t : [0; 2\pi] \rightarrow F_t$ for a $t \in T$ sufficiently near to p , which intersects each T_i .

Indeed, it can be shown, that $\gamma_t(2\pi)$ is independent of the choices of p_i , T_i and the chosen paths γ_t . Moreover, $\gamma_t(2\pi)$ only depends on the homotopy class of γ . Hence we get a map

$$h : \pi_1(F, p) \longrightarrow \text{Aut}(T, p),$$

where $\pi_1(F, p)$ is the fundamental group of F with respect to p and $\text{Aut}(T, p)$ denotes the germs of automorphisms of T which fix p . We call

$$\text{Hol}(F, p) := h(\pi_1(F, p))$$

the holonomy of the leaf F . Indeed, $\text{Hol}(F, p)$ is independent of the base point p , so that we will denote this by $\text{Hol}(F)$. For more details of the construction we refer to [CN].

2.3 The foliation of an integrable one-form

Let M be a real manifold of dimension $n+1$, ω a C^r one-form on M . Thus, for each $p \in M$

$$\omega(p) : T_p M \rightarrow \mathbb{R}$$

is a linear mapping. Setting

$$P(p) := \ker \omega(p),$$

where $\omega(p) \neq 0$, an n -plane field P is defined on M .

Frobenius' Theorem yields that P is induced by a codim-1-foliation on M if and only if P is completely integrable, which is equivalent to the condition

$$\omega \wedge d\omega = 0$$

on M (see [CN, Ch.II § 4, Appendix § 3 Th.2]).

Thus, each completely integrable C^r one-form ω on M with $\omega(p) \neq 0$ in M induces a C^r codim-1-foliation $\mathcal{F} = \mathcal{F}(\omega)$ on M , where for $p \in F$, $F \in \mathcal{F}$

$$T_p F = \ker \omega(p).$$

Now, considering the corresponding foliation charts of M , the *local* existence of Euler's multiplier is clear.

Moreover, the global existence of Euler's multiplier easily implies that $\text{Hol}(F) = \{1\}$ for all leaves F .

Also note that the foliation given by an integrable, nowhere vanishing one-form ω is transversely orientable: By using a partition of unity one can easily construct a C^r vector field X satisfying $\omega(X) \equiv 1$.

Finally, we want to mention the Godbillon-Vey class of $\mathcal{F}(\omega)$ (see [GV71]), if $r \geq \dim M \geq 3$. Since $\omega \wedge d\omega = 0$, we can find a one-form η such that $d\omega = \omega \wedge \eta$. Now the Godbillon-Vey class is defined

$$gv(\omega) := [-\eta \wedge d\eta] \in H^3(M, \mathbb{R})$$

as a de Rham class. Taking the cohomological class instead of the form itself has the effect, that $gv(\omega) = gv(f\omega)$ for any non-vanishing $f \in C^r(M)$. So it depends only on the foliation, not on the one-form. If ω allows for Euler's multiplier, $gv(\omega) = 0$.

3 Transverse fibrations

For the sake of simplicity, in this section all manifolds and maps are considered to be C^∞ unless stated otherwise. A fibre bundle $\phi : M \longrightarrow B$ with M, B being manifolds is called *transverse to the foliation $\mathcal{F}$ on M* , if and only if

$$\phi|_F : F \longrightarrow B$$

is an unramified, surjective covering map for every leaf F and therefore, in particular,

$$T_p M = T_p F \oplus T_p M_{\phi(p)},$$

where $p \in F$ and $M_{\phi(p)} := \phi^{-1}(\phi(p))$ is the fibre of ϕ over $\phi(p)$. In this situation we will also say, that $\mathcal{F}$ is *transverse to ϕ* . In our context, we assume, that $\dim M = n+1$ and $\dim B = n$ and hence, that $\mathcal{F}$ is a codimension one foliation.

For such ϕ we can define a *global* version of holonomy in the following way. Given a closed path $\alpha : [0; 2\pi] \longrightarrow B$ on B and a point $y \in \phi^{-1}(\alpha(0)) := T$, we can look at the lifting $\tilde{\alpha} : [0; 2\pi] \longrightarrow F_y$ on the leaf F_y containing y with $\tilde{\alpha}(0) = y$. Mapping $y \mapsto \tilde{\alpha}(2\pi)$ induces a C^r diffeomorphism $\phi_\alpha : T \longrightarrow T$. In fact, ϕ_α only depends on the homotopy class of α . So we get a representation

$$\mathbf{h} : \pi_1(B) \longrightarrow \text{Diff}^r(T),$$

where $\pi_1(B)$ is the fundamental group of B and $\text{Diff}^r(T)$ the group of C^r automorphisms of T . We call the image of $\mathbf{h}$ the global holonomy group (with respect to ϕ) of $\mathcal{F}$ and denote this by $\text{Hol}(\mathcal{F}/B)$. For details see again [CN].

As $\phi|_F : F \longrightarrow B$ is a covering map, we can embed $\pi_1(F) \subset \pi_1(B)$ and look at the restricted map

$$\mathbf{h}|_F : \pi_1(F) \longrightarrow \text{Diff}^r(T),$$

whose image we call $\widetilde{\text{Hol}}(F)$, on the one hand and at the ordinary holonomy map

$$h_F : \pi_1(F) \longrightarrow \text{Hol}(F)$$

on the other hand, both of them are group homomorphisms. By definition of $\mathbf{h}$ follows that

$$\ker(\mathbf{h}|_F) \subset \ker(h_F)$$

and hence there is a surjective homomorphism

$$\widetilde{\text{Hol}}(F) = \pi_1(F)/\ker(\mathbf{h}|_F) \longrightarrow \pi_1(F)/\ker(h_F) = \text{Hol}(F)$$

We now proved that $\text{Hol}(F)$ is a quotient of a subgroup of $\text{Hol}(\mathcal{F}/B)$ for every leaf F .

So $\text{Hol}(\mathcal{F}/B) = 1$ implies $\text{Hol}(F) = 1$ for all leaves F , but the converse is not true.

Theorem 3.1 *Let $\phi : M \longrightarrow B$ a fibre bundle and $\mathcal{F}$ a transverse codim-1-foliation, both of class C^r . Then are equivalent:*

- (a) *There is a C^r function $f : M \longrightarrow \mathbb{R}$ such that $df(x) \neq 0$ in M and $\mathcal{F} = \mathcal{F}(df)$.*
- (b) *$\text{Hol}(\mathcal{F}/B) = 1$ and the fibres of ϕ are diffeomorphic to $\mathbb{R}$.*

In particular, $M \cong B \times \mathbb{R}$ if one (and hence both) of the conditions is satisfied.

Proof: $\Rightarrow$: Let F be a leaf and T a fibre of ϕ , meeting in a point $p \in M$. Then we obtain a non-vanishing vector field X along T satisfying

$$df|_T(X) > 0$$

Now let $\gamma : [0, y] \rightarrow T$ be a differentiable path in T such that

$$d\gamma(t)(1) = X(\gamma(t)),$$

By Stokes' Theorem $f(\gamma(y)) - f(\gamma(0)) > 0$. So T is diffeomorphic to $\mathbb{R}$ and intersects each leaf exactly once. This implies $\text{Hol}(\mathcal{F}/B) = 1$, in particular.

$\Leftarrow$: Let T be a fibre of ϕ . The condition $\text{Hol}(\mathcal{F}/B) = 1$ implies that T intersects each leaf F in exactly one point. This means that there is a differentiable map $\psi : M \rightarrow T$. Now take a diffeomorphism $\delta : T \rightarrow \mathbb{R}$ and define $f := \delta \circ \psi$. Then the leaves of $\mathcal{F}$ are the level sets of f . The construction easily yields $df(x) \neq 0$ everywhere. $\square$

Let us recall that the relative tangent bundle $T_{M|B}$ is defined by

$$T_{M|B,x} = di_x(T_x M_{\phi(x)}),$$

where $M_{\phi(x)}$ is again the fibre over $\phi(x)$, $i : M_{\phi(x)} \rightarrow M$ the natural embedding and di_x the derivative of i at x , embedding the tangent bundle of the fibre into the tangent bundle of M . The i -th Betti number of a manifold B is denoted by $b_i(B) = \dim H^i(B, \mathbb{R})$.

Definition 3.2 Let M be a manifold and $\phi : M \rightarrow B$ a fibre bundle. We call M ϕ -orientable if and only if $T_{M|B}$ is orientable.

Theorem 3.3 Let M, B be manifolds, $\phi : M \rightarrow B$ a fibre bundle such that $\dim M = \dim B + 1$ and M is ϕ -orientable. If $b_2(B) = 0$, then there is a transverse and transversely orientable foliation $\mathcal{F}$ and a Riemannian metric on M such that $T_{M|B} = T_{\mathcal{F}}^\perp$ and all fibres of π are geodesics.

If B is simply connected, then every transverse foliation $\mathcal{F}$ is transversely orientable.

Proof: By general theory [CN, Ch. V, §4] any two transverse foliations $\mathcal{F}, \mathcal{F}'$ with the same global holonomy are equivalent, i.e. there is some $H \in \text{Diff}(M)$ such that $\phi \circ H = \phi$ and takes leaves of $\mathcal{F}$ to leaves of $\mathcal{F}'$. If $\mathcal{F}' = \mathcal{F}(\omega)$ for an integrable one-form ω , then $H^*\omega$ is an integrable one-form and $\mathcal{F} = \mathcal{F}(H^*\omega)$. Furthermore $\text{Hol}(\mathcal{F}/B) = 1$ for all transverse foliations $\mathcal{F}$, if $\pi_1(B) = 1$. So it is sufficient to construct an integrable one-form ω such that $\mathcal{F}(\omega)$ is transverse to ϕ .

By assumption, M is ϕ -orientable and hence there is a non-vanishing vector field $X \in T_{M|B}$. For any $p \in M$ we can find a chart $V \subset B$ such that $\phi^{-1}(V) \cong C \times V$, C being the fibre. After a choice of a section S of Φ over V we can introduce the fibre coordinate t of $x \in \phi^{-1}(V)$ by $x = \alpha_X(t)$; here α denotes the flow of the subscript vector field starting in $S(\phi(x))$. If $C \cong \mathbb{R}$, then dt is a well defined one-form on $\phi^{-1}(V)$. If $C \cong S^1$, then we can achieve

$$\alpha_X(t) = \alpha_X(t+1)$$

by multiplying X with a nonvanishing global function, independently of the choice of S . Given this property, the one-form dt is well defined on $\phi^{-1}(V)$.

If we now think of $M = \bigcup_i C \times V_i$ to be covered by such charts, in the intersection $C \times (V_i \cap V_j)$ we have

$$dt^{(i)} = dt^{(j)} - \phi^* \eta_{ij}$$

on $\phi^{-1}(V_i \cap V_j)$ for a closed one-form $\eta_{ij} \in \mathcal{A}_B^1(V_i \cap V_j)$ depending on the sections S_i and S_j . Let us denote by $\mathcal{K} \subset \mathcal{A}_B^1$ the sheaf of closed one-forms on B . If we knew $H^1(B, \mathcal{K}) = 0$, then we could find closed one-forms $\eta_i \in \mathcal{A}_B^1(V_i)$ such that $\eta_{ij} = \eta_i - \eta_j$ on $V_i \cap V_j$. Thus

$$\omega := dt^{(i)} + \phi^* \eta_i$$

would define a global closed one-form with $\omega(X) = 1$, yielding a transverse and transversely orientable foliation.

In order to compute $H^1(B, \mathcal{K})$ note that

$$0 \longrightarrow \mathcal{K} \longrightarrow \mathcal{A}_B^1 \xrightarrow{d} \mathcal{A}_B^2 \xrightarrow{d} \dots$$

is an acyclic resolution abbreviating the standard acyclic resolution of $\mathbb{R}$ by one step. So we find $H^1(B, \mathcal{K}) = H^2(B, \mathbb{R}) = 0$.

After an appropriate choice of a Riemannian metric g_B on B we can construct a Riemannian metric

$$g := \omega \otimes \omega + \phi^* g_B$$

on M . The geodesic equation for the fibre is $\Gamma_{11}^i = 0$, first for all $i > 1$, but then also for $i = 1$, since geodesics are parametrised proportional to arc length. This translates to $\omega_{i,1} = 0$, a condition satisfied since ω is closed and $\omega_1 = 1$. Finally, if $\tau \in T_{\mathcal{F},x}$ we compute

$$g\left(\frac{\partial}{\partial t}, \tau\right) = \omega\left(\frac{\partial}{\partial t}\right)\omega(\tau) + \phi^* g_B\left(\frac{\partial}{\partial t}, \tau\right) = 0 + 0 = 0,$$

so $T_{M|B} = T_{\mathcal{F}}^\perp$.

□

Example 3.4 Every circle bundle (with structure group $U(1) \subset \text{Aut}(S^1)$, that is) $\pi : M \longrightarrow B$ is π -oriented. So, if B is a manifold such that $H^2(B, \mathbb{Z})$ is a torsion group, every non-zero element of $H^2(B, \mathbb{Z})$ induces a non-trivial circle bundle over B satisfying the assumptions of the theorem. For example, real projective space of dimension ≥ 2 or every complex Inoue surface is such a base manifold B . $\triangle$

Up to now, in all cases, for which we proved $\mathcal{F} = \mathcal{F}(df)$, we had $M/\mathcal{F} \cong \mathbb{R}$.

4 Regular foliations induced by integrable one-forms

We want to formulate regularity conditions in terms of global generatedness. For this purpose recall a relative version of this.

Definition 4.1 For any sheaf $\mathcal{E}$ on a topological space M and continuous map $\psi : M \longrightarrow N$ to a topological space N we say that $\mathcal{E}$ is ψ -generated, if for all $x \in M$, open sets $U \subset M$ with $x \in U$ and $f \in \mathcal{E}(U)$ there exist $V \subset U, W \subset N$ open and $\tilde{f} \in \mathcal{E}(\psi^{-1}(W))$ such that $x \in V \cap \psi^{-1}(W)$ and $\tilde{f}|V = f|V$. We say $\mathcal{E}$ is *globally generated*, if ψ can be chosen to be the constant map.

For foliations there is natural sheaf to consider.

Definition 4.2 Let M be a C^r manifold and $\mathcal{F}$ be a C^r foliation. For any open set $U \subset M$ we denote

$$C_{\mathcal{F}}^r(U) := \{f \in C^r(U) | f \text{ is constant on the leaves of } \mathcal{F}|U\}$$

Definition 4.3 (a) For leaves F, F' of a C^r foliation $\mathcal{F}$ on M we say F is *infinitely close* to F' , if for any saturated open sets $U \supset F, U \supset F'$ holds $U \cap U' \neq \emptyset$. The smallest equivalence relation generated by this property is denoted by $\sim$, its quotient by G and $p : M/\mathcal{F} \longrightarrow G$ the quotient map. Finally, let $S := \{F \in \mathcal{F} | p^{-1}(p(F)) \neq \{F\}\}$ denote the *non-Hausdorff leaves* of $\mathcal{F}$.

(b) The foliation $\mathcal{F}$ is called *of finite type*, if

- (i) each leaf $F \in \mathcal{F}$ is closed,
- (ii) $p(S)$ is a discrete subset of G , and for each $g \in G$ the set $p^{-1}(g)$ is finite.

(c) For a C^r -foliation $\mathcal{F}$ on M we call $\tilde{M}_{\mathcal{F}} := (N_{\mathcal{F}} \setminus (\{0\} \times M))/\mathbb{R}^+$ the $\mathcal{F}$ -oriented double cover of M ; here $\mathbb{R}^+$ acts by multiplication on the fibres. We denote the natural projection by $\alpha : \tilde{M}_{\mathcal{F}} \longrightarrow M$ and obtain a foliation $\tilde{\mathcal{F}} := \alpha^* \mathcal{F}$ with projection maps $\tilde{\pi} : \tilde{M}_{\mathcal{F}} \longrightarrow \tilde{M}_{\mathcal{F}}/\tilde{\mathcal{F}}$ and $\tilde{p} : \tilde{M}_{\mathcal{F}}/\tilde{\mathcal{F}} \longrightarrow \tilde{G}$. The foliation $\tilde{\mathcal{F}}$ is transversely orientable.

(d) A C^r -foliation $\mathcal{F}$ on M is called *regularly C^r* , if the sheaves $\tilde{\pi}_* C_{\tilde{\mathcal{F}}}^s$ are globally generated for all $1 \leq s \leq r$. If $r = \infty$, we call $\mathcal{F}$ *regularly C^∞* , if $\tilde{\pi}_* C_{\tilde{\mathcal{F}}}^\infty$ is globally generated.

(e) A C^r -foliation $\mathcal{F}$ on M is called *almost regularly C^r* , if the sheaves $\tilde{\pi}_* C_{\tilde{\mathcal{F}}}^s$ are $\tilde{p}$ -generated for all $1 \leq s \leq r$; if $r = \infty$, we impose only $\tilde{\pi}_* C_{\tilde{\mathcal{F}}}^\infty$ to be $\tilde{p}$ -generated.

The seemingly complicated definition of regularity stems from the effort to separate the combinatorial data of $\mathcal{F}$ from its analytic. If we would have replaced the $\mathcal{F}$ -oriented double cover of M simply by M , non-regularity could have occurred just for combinatorial reasons, e.g. the foliation in Figure 3(c) would be non-regular, independently of the analytic behaviour of the leaves near F'_1, F'_2, F'_3 . The $\mathcal{F}$ -oriented double cover in this case would have six equivalent non-Hausdorff leaves (with micrograph being a hexagon, cf. next chapter) and the well-meaning reader may agree that the extension property given in the definition of regularity holds in this case. We will see later that non-regularity is a crucial obstruction for a foliation of finite type to be characterized by combinatorial data. So we want to inquire into conditions for a foliation of finite type to be regular.

Our main question is: When is a foliation induced by a one-form regular? For the sake of simplicity we restrict ourselves to the case of C^∞ regularity. The corresponding results for C^r -regularity are similar and obtained in the same way.

Lemma 4.4 *Let ω be an integrable C^∞ one-form without zeroes on the C^∞ manifold M . If the foliation $\mathcal{F}(\omega)$ is of finite type and there exists $\lambda \in C^\infty(M)$ such that $\omega \wedge d\lambda = d\omega$, then $\mathcal{F}(\omega)$ is regularly C^∞ .*

Proof: Let X be a C^∞ vector field on M such that $\omega(X) \equiv 1$. This can easily be constructed using a partition of unity. Now we consider the flow α_t of hX for a $h \in C^\infty(M)$. We want to choose h in such a way that leaves will be mapped to leaves (where defined), i.e. for any leaf F and its inclusion $i_F : F \hookrightarrow M$ we want $i_F^* \alpha_t^* \omega = 0$ for all admissible t . Furthermore no leaf shall be fixed, i.e. h is wanted without zeroes. Differentiating this equation by t and looking at $t = 0$ yields

$$\mathcal{L}_{hX} \omega \wedge \omega = 0,$$

where $\mathcal{L}$ denotes the Lie derivative.

On the other hand, $\mathcal{L}_{hX} \omega \wedge \omega = 0$ implies $\mathcal{L}_{hX} \omega = \kappa \omega$ for some $\kappa \in C^\infty(M)$ and we compute

$$\frac{d}{dt} i_F^* \alpha_t^* \omega = i_F^* \frac{d}{dt} \alpha_t^* \omega = i_F^* \alpha_t^* \mathcal{L}_{hX} \omega = \kappa i_F^* \alpha_t^* \omega,$$

hence

$$i_F^* \alpha_t^* \omega = C \exp(\kappa t) i_F^* \omega = 0$$

So our derived equation is indeed equivalent to the leaf preserving property of the flow.

By elementary rules (see e.g. [La]) we compute

$$\begin{aligned} \mathcal{L}_{hX} \omega &= h \mathcal{L}_X \omega + \omega(X) dh \\ &= h d(\omega(X)) + h C_X d\omega + dh \\ &= h C_X d\omega + dh. \end{aligned}$$

Here C denotes the contraction map. Note furthermore that $C_X d\omega \wedge \omega = C_X (d\omega \wedge \omega) - \omega(X) d\omega = -d\omega$. So our leaf conserving equation reads

$$dh \wedge \omega = h d\omega,$$

or, assuming $h > 0$ and defining $\lambda := \log h$,

$$d\lambda \wedge \omega = d\omega$$

Now we can choose foliation charts such that hX is the tangent vector associated to the non-leaf coordinate function if and only if h is nowhere zero. These foliation charts patch together to give an almost regular C^∞ foliation due to the non-vanishing of h : Let $f \in C^\infty(U)$ for a saturated open set U , $F \subset U$ a leaf and F' infinitely close to F . We find $\varepsilon > 0, x \in F, x' \in F'$ such that

$$\psi : (-\varepsilon, \varepsilon) \longrightarrow M, t \mapsto \alpha_t(x) \text{ and } \psi' : (-\varepsilon, \varepsilon) \longrightarrow M, t \mapsto \alpha_t(x')$$

are well-defined. Due to the facts that F and F' are infinitely near and hX is leaf-preserving, we have that the points $\psi(t)$ and $\psi'(t)$ are on the same leaf whenever $\psi'(t)$ is on a leaf contained in $U \cap \psi((-\varepsilon, \varepsilon))$. Let U' be the saturation of $\psi'((-\varepsilon, \varepsilon))$. Since $d\psi'(0) = h(x')X(x') \neq 0$, we may assume that U' is open. Furthermore, since

$\mathcal{F}$ is transversely orientable and all leaves are closed we may assume that $\pi \circ \psi$ and $\pi \circ \psi'$ are injective with non-vanishing differentials. So the function

$$\tilde{f} : U \cup U' \longrightarrow \mathbb{R}, z \mapsto \begin{cases} f(z) & , \text{ if } z \in U \\ f(\psi(t)) & , \text{ if } z = \psi'(t) \in U' \end{cases}$$

is well-defined, an element of $C_{\mathcal{F}}^{\infty}(U \cup U')$ and extends f beyond F' . By the way of construction, these extensions glue together to yield an extension $\tilde{f}'$ of f on a saturated open set $\tilde{U} \supset [F]_{\sim} \cup U$, since $\mathcal{F}$ is of finite type. The same assumption about $\mathcal{F}$ allows us to extend $\tilde{f}'|_{\tilde{V}}$ to a function $\tilde{f} \in C_{\mathcal{F}}^{\infty}(M)$ vanishing outside $\tilde{U}$ for a shrunk saturated open set $U \cup [F]_{\sim} \subset \tilde{V} \subset \tilde{U}$. So $\mathcal{F}$ is regularly C^{∞} . $\square$

This implies immediately that $\mathcal{F}(\omega)$ is regular, if it is of finite type and ω is closed. The reader will agree that the proof of Lemma 4.4 is also valid to prove almost regularity, if the condition on $\mathcal{F}$ to be of finite type is relaxed appropriately. The first order differential equation characterizes that some multiple of ω is closed:

Lemma 4.5 $\omega \wedge d\lambda = d\omega$ has a global solution $\lambda \in C^{\infty}(M) \iff \exists h \in C^{\infty}(M)$ positive such that $h\omega$ is closed.

Proof: For any positive function $h \in C^{\infty}(M)$ and global solution λ of $\omega \wedge d\lambda = d\omega$, the function $\tilde{\lambda} := \lambda - \log h$ solves $\tilde{\omega} \wedge d\tilde{\lambda} = d\tilde{\omega}$ for $\tilde{\omega} := h\omega$. Hence we choose $h := \exp(\lambda)$ in order to achieve $\tilde{\lambda} = 0$. If $h\omega$ is closed, then $0 = h d\omega + dh \wedge \omega$, hence $\log h$ is a global solution of the equation. $\square$

The C^{∞} integrable one-form ω induces a canonical element $[\omega] \in H^1(M, C_{\mathcal{F}}^{\infty})$ via the following construction. Let $\omega = f_i dg_i$ on U_i as constructed by Frobenius' Theorem and $\lambda_i := \log |f_i|$. This is a solution to the differential equation in Lemma 4.5, so $d(\lambda_i - \lambda_j) \wedge \omega = 0$ on $U_i \cap U_j$, i.e. $\phi_{ij} := \lambda_i - \lambda_j \in C_{\mathcal{F}}^{\infty}(U_{ij})$. If the covering U_i is chosen fine enough, the functions ϕ_{ij} define an element $[\omega] \in H^1(M, C_{\mathcal{F}}^{\infty})$ independent of the choices made.

Proposition 4.6 Let M be a C^{∞} manifold, ω a nowhere vanishing integrable C^{∞} one-form and $\mathcal{F} = \mathcal{F}(\omega)$ of finite type. For the properties

- (a) $[\omega] = 0 \in H^1(M, C_{\mathcal{F}}^{\infty})$,
- (b) $\mathcal{F}$ is induced by a closed one-form,
- (c) $\mathcal{F}$ is regularly C^{∞}

holds: (a) $\Rightarrow$ (b) $\Rightarrow$ (c).

Proof:

'(a) $\Rightarrow$ (b)': We construct ϕ_{ij} like above. Property (a) now yields $\phi_i \in C_{\mathcal{F}}^{\infty}(U_i)$ such that $\lambda_i + \phi_i = \lambda_j + \phi_j$ on $U_i \cap U_j$. So we obtain a global solution $\lambda \in C^{\infty}(M)$ for $d\lambda \wedge \omega = d\omega$.

The implication (b) $\Rightarrow$ (c) is already proved. $\square$

If $\mathcal{F}(\omega)$ is given by a closed one-form, then $gv(\omega) = 0$, of course. Note that the property $gv(\omega) = 0$ is much weaker than the property that $\mathcal{F}$ is given by a closed one-form. In case of $M = \mathbb{R}^3$ a smooth version of the first example of the introduction

(leaves winding around a cylinder) cannot be given by a closed one-form, but $gv(\omega) = 0$, since $b_3(R^3) = 0$.

Regularity will turn out to be the main assumption in order to enable us to decide the existence of Euler's multiplier from graphical data constructed in the next section (cf. proofs of Lemma 5.17 and Theorem 5.18).

5 The graphical configuration of a foliation and the existence of Euler's multiplier

If $M/\mathcal{F}$ is a one-dimensional real manifold diffeomorphic to $\mathbb{R}$, it is now clear that there is some function $f \in C^1(M, \mathbb{R})$ with

$$(3) \quad \forall x \in M : \quad df(x) \neq 0, \quad \text{and} \quad \mathcal{F} = \mathcal{F}(df).$$

Roughly speaking, in what follows, we are going to decompose $M/\mathcal{F}$ into manifolds diffeomorphic to $\mathbb{R}$ and investigate consistency at the connecting points. The global existence of f as in (3) then depends on a certain geometric and topological configuration of $M/\mathcal{F}$ which can be described by graphs.

The components of $M/\mathcal{F}$ which are manifolds diffeomorphic to $\mathbb{R}$ are identified with the edges of a graph, in the following called the *macrograph* of $M/\mathcal{F}$. The vertices of this macrograph correspond to the irregular points of $M/\mathcal{F}$, i.e., points that are non-Hausdorff-points or endpoints of $M/\mathcal{F}$. For example, the leaves F_1 and F_2 in the foliation $\mathcal{F}$ in Fig. 3 (a) or the leaves F'_1, F'_2, F'_3 of $\mathcal{F}'$ in Fig. 3 (c) are such non-Hausdorff-points. (The marked point in Figure 3(c) where the leaves F'_1, F'_2, F'_3 meet together does not belong to M .) The corresponding (local) macrographs of

Figure 3: Examples of foliations with non-Hausdorff leaves

these “bifurcations” of $\mathcal{F}$ or $\mathcal{F}'$ are the same and will look like in Fig. 3 (b) or Fig. 3 (d), respectively. The macrographic configuration of a foliated manifold is not alone decisive for the existence of f with the properties mentioned above. The foliation $\mathcal{F}'$ in Fig. 2 has the same macrographic configuration as $\mathcal{F}$, but obviously, $\mathcal{F}$ admits such a function f as in (3), whereas $\mathcal{F}'$ does not so.

Therefore, the behaviour of the foliation $\mathcal{F}$ in the irregular points of $M/\mathcal{F}$ is to be taken into account. It will be described by so-called *micrographs*.

The growth of f , if it exists, will later be denoted by an orientation of the edges of the macrograph. The micrograph in a vertex of the macrograph regulates the

“traffic”, i.e., tells us along which ways in $M/\mathcal{F}$ the function f is increasing. Therefore the macroedges beginning or ending in some macrovertex are identified with the vertices in the micrograph. The microedges are the irregular points of $M/\mathcal{F}$ and connect the two macroedges from which they are accessible.

For example, the foliations in Figure 3 have in the macrovertices, displayed as bullets in Figure 3(b) and (d), the micrographs as in Figure 4. The system consisting of

Figure 4: Corresponding micrographs to the examples above

the macrograph Γ and the micrographs γ_σ in the vertices $\sigma \in \Gamma$, integrated in Γ , is called the graphical configuration of $M/\mathcal{F}$ and is decisive for the global existence of Euler's multiplier.

It will turn out that two criteria, one on the micrographs and one on the macrograph, are necessary and, together with some topological conditions on the leaves of $\mathcal{F}$, also sufficient for the global existence of Euler's multiplier.

In a first step, supposing only the first criterion, we will prove the *semiglobal* existence, i.e., if all micrographs admit the globalization of f , then for each $p \in M$ there is a neighbourhood $\tilde{U} \subset M$ of F_p and, should the occasion arise, all other leaves belonging to the same macrovertex as F_p (see Def. 4.3(a), Def. 5.3), saturated with respect to $\mathcal{F}$, such that in $\tilde{U}$ Euler's multiplier can be defined. In this case, if the orientation of one macroedge is chosen, the micrographs of the macrovertices connected to this macroedge determine the orientation of the neighbouring macroedges.

If this condition of semiglobal existence is fulfilled, then the orientability of the macrograph with respect to the regulation of the micrographs and the topological properties of the oriented macrograph decide about the global existence.

In particular, if M is simply connected, the macrograph and the micrographs of $\mathcal{F}$ are also simply connected. By the latter property semiglobal existence is guaranteed, but this even implies global existence by the simply connectedness of the macrograph.

In Figure 5 the graphs of three foliations corresponding to the same macrographs are shown. The edges of the macrograph are represented by dotted lines, the edges of the micrographs of the macrovertices by full lines. The terms *locally eulerian* and *globally eulerian* are defined in 5.13.

The ideas mentioned above shall be stated more precisely in the following.

5.1 Construction of the graph of a foliation

Having discussed foliations of a certain type in the previous chapter, we want to go into greater detail here and therefore give them a name.

Figure 5: Examples of locally or globally eulerian configurations

Definition 5.1 Let M be a real C^r -manifold of dimension $n+1$, $\mathcal{F}$ a codim-1-foliation of class C^r on M . The foliation $\mathcal{F}$ is called *graphical* if and only if it is of finite type and regularly C^r .

If a Jordan Brouwer separation theorem holds on M , we can show that the two conditions in the definition of finite type foliations are not independent. This is done in §6.

Note that the finiteness of $p^{-1}(g)$ for each $g \in G$ implies that G is Hausdorff.

In what follows, we assume $\mathcal{F}$ to be a graphical foliation on a real manifold M according to Definition 5.1. Now we are in a position to construct the macrograph

Definition 5.2 (Endpoints) Let $e \in M/\mathcal{F}$. We say that e is an *endpoint* if and only if there exists some $a \in M/\mathcal{F}$ such that for each continuous injective mapping $w : [0, 1] \rightarrow M/\mathcal{F}$ with $w(0) = a$ and $e \in w([0, 1])$ holds $w(1) = e$. Moreover, let E denote the set of endpoints in $M/\mathcal{F}$.

For example, the leaf F in Figure 6 is such an endpoint.

Figure 6: Example of an endpoint

of the foliation $\mathcal{F}$.

Construction 5.3 (Macrograph) (a) *Vertices*: If $(S/\sim) \cup (E/\sim) = \emptyset$ take an arbitrary $\sigma \in G$ and set $\mathcal{V}\Gamma^0 := \{\sigma\}$, else let

$$\mathcal{V}\Gamma^0 := (S/\sim) \cup (E/\sim).$$

Let us define recursively: (i) If there is a continuous injective mapping $w : [0, 1) \rightarrow G$ with $w(0) = \sigma_1 \in \mathcal{V}\Gamma^j$ and $w((0, 1)) \subset G \setminus \mathcal{V}\Gamma^j$ and the limit $\lim_{t \rightarrow 1} w(t)$ does not exist, then define

$$\mathcal{V}\Gamma^{j+1} := \mathcal{V}\Gamma^j \cup \bigcup_{k \in \mathbb{N}} w\left(1 - \frac{1}{k}\right).$$

(ii) If there is an injective mapping $w : [0, 1) \rightarrow G$ with $w(0) = \sigma_1 \in \mathcal{V}\Gamma^j$ and $w((0, 1)) \subset G \setminus \mathcal{V}\Gamma^j$ and $\lim_{t \rightarrow 1} w(t) = w(0) = \sigma_1$ then define

$$\mathcal{V}\Gamma^{j+1} := \mathcal{V}\Gamma^j \cup w\left(\frac{1}{2}\right).$$

As there can only be a countable number of ranges $w((0, 1)) \subset G$, by choice of a counting it can be obtained that

$$\mathcal{V}\Gamma := \bigcup_{j \in \mathbb{N}} \mathcal{V}\Gamma^j$$

has the property that $w(1) := \lim_{t \rightarrow 1} w(t)$ does exist for every continuous, injective map $w : [0, 1] \rightarrow G$ with $w(0) = \sigma_1 \in \mathcal{V}\Gamma$ and $w((0, 1)) \subset G \setminus \mathcal{V}\Gamma$, where $w(1) \neq w(0)$. Now $\mathcal{V}\Gamma$ is called the set of *vertices* of the macrograph Γ . Note that $S \subset p^{-1}(\mathcal{V}\Gamma)$, but, in general, there are also noncritical vertices (cf. Remark 5.4).

(b) *Edges*: To define the edges of the macrograph first we set

$$\mathbf{W} := \left\{ w : [0, 1] \rightarrow M/\mathcal{F} \mid w \text{ is continuous, } w|_{[0,1)} \text{ is injective, } \right. \\ \left. w(0), w(1) \in p^{-1}(\mathcal{V}\Gamma), w((0, 1)) \cap p^{-1}(\mathcal{V}\Gamma) = \emptyset \right\}.$$

Now we say $w \sim^* w'$ for $w, w' \in \mathbf{W}$ if and only if

$$p(w([0, 1])) = p(w'([0, 1]))$$

For each $L \in \mathbf{W} / \sim^*$ set an edge L connecting the corresponding points $p(w(0))$ and $p(w(1))$ in $\mathcal{V}\Gamma$, i.e., let $\mathcal{E}\Gamma := \mathbf{W} / \sim^*$ be the set of edges of Γ .

Now we can define the macrograph $\Gamma = (\mathcal{V}\Gamma, \mathcal{E}\Gamma)$ with the corresponding mapping

$$(4) \quad \kappa : \mathcal{E}\Gamma \rightarrow S^2\mathcal{V}\Gamma, L \mapsto \{p(w(0)), p(w(1))\}, \quad \text{where } [w]_{\sim^*} = L.$$

For $x \in M$ and $L \in \mathcal{E}\Gamma$ we will write

$$(5) \quad x \in L :\Leftrightarrow \exists w \in \mathbf{W} : [w]_{\sim^*} = L, \pi(x) \in w((0, 1)).$$

Remark 5.4 The construction in 5.3 (a) guarantees that each edge of Γ connects two different vertices. This is due to the formal definition of graphs in literature. The addition (i) is necessary to avoid edges running to infinity and is illustrated in Figure 7. The addition (ii) suppresses loops in Γ by adding a 'noncritical' vertex.

Figure 7: construction (i) in 5.3

Figure 8: construction (ii) in 5.3

An example of a foliation generating such a loop and the corresponding macrograph is shown in Figure 8. Here, the leaves F_1 and F_2 are non-Hausdorff and generate the first vertex. Note that these 'artificial' vertices have trivial inner structure and are therefore noncritical, cf. Remark 5.6.

Now we investigate the macrovertices and construct the corresponding micrographs.

Construction 5.5 (Micrograph) Let $\sigma \in \mathcal{V}\Gamma \setminus (E/\sim)$, $p^{-1}(\sigma) = \{s_1, \dots, s_N\} \subset M/\mathcal{F}$. Let $\mathcal{E}\Gamma^\sigma := \{L_1, \dots, L_\nu\}$ be the set of macroedges L with $\sigma \in \kappa(L)$, where κ is defined in (4).

(a) *Vertices*: Let

$$\mathcal{V}\gamma_\sigma := \{L_1, \dots, L_\nu\}$$

be the set of vertices of the micrograph γ_σ of the macrovertex σ .

(b) *Edges*: We say for $s \in p^{-1}(\mathcal{V}\Gamma)$ and $L \in \mathcal{E}\Gamma$

$$s \in \text{Lim}(L) :\iff \exists w \in \mathbf{W} : [w]_{\sim^*} = L, w(1) = s.$$

Now we will show that for each leaf $s_j \in p^{-1}(\sigma)$ there are exactly two different macroedges L with $s_j \in \text{Lim}(L)$:

Since $s = s_j \in p^{-1}(\sigma)$ is no endpoint, there is a continuous bijective mapping $w : [0, 1] \rightarrow M/\mathcal{F}$ with $s \in w((0, 1))$. Let $\tau \in (0, 1)$ with $w(\tau) = s$. Extending and rescaling $w|_{[0, \tau]}$ and $w|_{[\tau, 1]}$ in an appropriate way we can obtain two different macroedges $[w_1]_{\sim^*}$ and $[w_2]_{\sim^*}$ with $s \in \text{Lim}([w_1]_{\sim^*}) \cap \text{Lim}([w_2]_{\sim^*})$. Thus there are at least two macroedges connected to s . Now let $x \in s \subset M$ be any fixed point and (U, φ) a foliation chart of $(M, \mathcal{F})$, where $x \in U$, $D \subset \mathbb{R}^n$, $I = (-\epsilon, +\epsilon)$ and $\varphi = (\varphi_1, \varphi_2) : U \rightarrow D \times I$ is a bijective C^r mapping. Now consider the commutative diagram

$$\begin{array}{ccc} M \supset U & \xrightarrow{\varphi} & D \times I, \\ \downarrow \pi & & \downarrow pr \\ M/\mathcal{F} \supset V & \xrightarrow{i_V} & I \end{array}$$

where $V = \pi(U)$ and i_V is, by definition of the local manifold structure of $M/\mathcal{F}$, a diffeomorphism. Without restriction we can assume $\varphi_2(x) = 0$ and therefore we have

$$i_V(w_j((0, 1)) \cap V) = (-\epsilon, 0) \text{ or } i_V(w_j((0, 1)) \cap V) = (0, +\epsilon), \quad j = 1, 2,$$

if $\epsilon > 0$ is sufficiently small. But $i_V(w_1((0, 1)) \cap V) = i_V(w_2((0, 1)) \cap V)$ implies already $[w_1]_{\sim^*} = [w_2]_{\sim^*}$. Thus, there are exactly two macroedges L satisfying $s \in \text{Lim}(L)$.

Now we set $\mathcal{E}\gamma_\sigma := \{s_1, \dots, s_N\}$. For $j = 1, \dots, N$ and $s \in \text{Lim}(L_{j_1}) \cap \text{Lim}(L_{j_2})$, where $L_{j_1} \neq L_{j_2}$ set the microedge s connecting the microvertices L_{j_1} and L_{j_2} . Now the micrograph γ_σ is given by $\gamma_\sigma = (\mathcal{E}\gamma_\sigma, \mathcal{V}\gamma_\sigma)$ with the corresponding mapping

$$(6) \quad \kappa_\sigma : \mathcal{E}\gamma_\sigma \rightarrow S^2\mathcal{V}\gamma_\sigma, \quad s_j \mapsto \{L_{j_1}, L_{j_2}\}.$$

Remark 5.6 Examples of micrographs are shown in Figure 4. The micrograph of a noncritical macrovertex has trivial structure which is displayed in Figure 9.

Figure 9: A micrograph of a noncritical macrovertex

Definition 5.7 (Graphical configuration) Let $\mathcal{F}$ be a graphical foliation on a real manifold M according to Definition 5.1, Γ the macrograph of $M/\mathcal{F}$ and γ_σ the micrographs of the macrovertices $\sigma \in \mathcal{V}\Gamma$ according to Constructions 5.3, 5.5. Then $\delta(F) := (\Gamma, (\gamma_\sigma)_\sigma)$ is called the *graphical configuration* of $\mathcal{F}$.

The following is just a refinement of [CN, Ch. 4, Lemma 5].

Lemma 5.8 *Let $\mathcal{F}$ be a foliation with only closed leaves on the manifold M . Then for every leaf F of $\mathcal{F}$ the holonomy is $\text{Hol}(F) \in \{1, \mathbb{Z}_2\}$. Furthermore, if $\mathcal{F}$ is graphical and $\text{Hol}(F) = \mathbb{Z}_2$ then $F \in E$, i.e. F is an endpoint of $\delta(\mathcal{F})$, where $\delta(\mathcal{F}) = (\Gamma, (\gamma_\sigma)_\sigma)$ is the graphical configuration of the foliation $\mathcal{F}$.*

The following notion of oriented and bipartite graphs will turn out to be appropriate for the criteria of existence of Euler's multiplier.

Definition 5.9 (Orientation) Let $\mathcal{G}$ be the macrograph Γ (or any other graph). Then a mapping

$$\uparrow : \mathcal{EG} \rightarrow \mathcal{VG} \times \mathcal{VG}$$

is called orientation of $\mathcal{G}$ if and only if $f \circ \uparrow = \kappa$, where

$$f : \mathcal{VG} \times \mathcal{VG} \rightarrow S^2\mathcal{VG}, (\sigma_1, \sigma_2) \mapsto \{\sigma_1, \sigma_2\}.$$

Definition 5.10 (bipartite Graph) Let $\mathcal{G} = (\mathcal{VG}, \mathcal{EG})$ be a micrograph γ_σ or any other graph with corresponding mapping κ (cf. (6)). The graph $\mathcal{G}$ is called *bipartite* if and only if there exist two subsets $\mathcal{V}_+\mathcal{G}, \mathcal{V}_-\mathcal{G} \subset \mathcal{VG}$ with the following properties

- (a) $\mathcal{VG} = \mathcal{V}_+\mathcal{G} \cup \mathcal{V}_-\mathcal{G}, \quad \mathcal{V}_+\mathcal{G} \cap \mathcal{V}_-\mathcal{G} = \emptyset,$
- (b) $\forall s \in \mathcal{EG} \quad \exists L^+ \in \mathcal{V}_+\mathcal{G}, L^- \in \mathcal{V}_-\mathcal{G} : \quad \kappa(s) = \{L^+, L^-\}.$

The second condition means that only vertices of different classes are connected by edges of $\mathcal{G}$.

The micrographs of the first and the second example in Fig. 5 are bipartite, whereas two of the micrographs in the right example of Fig. 5 are not bipartite.

5.2 The foliation of a graphical configuration

We want to revert the construction of the graphical configuration. For this purpose we generalize Definition 5.7:

Definition 5.11 A *graphical configuration* is a tuple $(\Gamma, (\gamma_\sigma)_\sigma)$ with a graph Γ , graphs γ_σ for every $\sigma \in \mathcal{V}\Gamma$ such that $\mathcal{E}\Gamma^\sigma = \mathcal{V}\gamma_\sigma$.

For the definition of $\mathcal{E}\Gamma^\sigma$ see Construction 5.5.

Now we can prove

Theorem 5.12 *Let $\delta = (\Gamma, (\gamma_\sigma)_\sigma)$ be a graphical configuration without endpoints. Then there is closed one-form $\omega \neq 0$ on a surface M (maybe with zeroes), such that the zero locus of ω is smooth and has no zero-dimensional components, the leaves of the so defined foliation $\mathcal{F}(\omega)$ are diffeomorphic to $\mathbb{R}$ and $\delta = \delta(\mathcal{F}(\omega))$.*

Proof: Let $(\Gamma, \uparrow)$ be an orientation of Γ , that means

$$\mathcal{E}\Gamma \xrightarrow{\uparrow} \mathcal{V}\Gamma \times \mathcal{V}\Gamma \xrightarrow{f} S^2\mathcal{V}\Gamma,$$

where f is the forgetful map (forgetting the order) and $f \circ \uparrow = \kappa$, cf. Definition 5.9. Let us denote an element $m \in \mathcal{V}\Gamma \times \mathcal{V}\Gamma$ by (m_1, m_2) , and construct as follows. Let for $\sigma \in \mathcal{V}\Gamma, L \in \mathcal{E}\Gamma$ denote

$$\text{Lim}^\sigma(L) := \{s \in \mathcal{E}\gamma_\sigma \mid L \in \kappa_\sigma(s)\},$$

where κ_σ denotes the boundary map of γ_σ (cf. (6)). For every $L \in \mathcal{E}\Gamma$ define

$$I_L := [0, 1] \times (0, 1) \setminus (\{0\} \times \{\frac{i}{k} \mid i = 1, \dots, k-1\} \cup \{1\} \times \{\frac{i}{l} \mid i = 1, \dots, l-1\}),$$

if $\text{Lim}^{\uparrow_1(L)} L = \{s_{11}(L), \dots, s_{1k}(L)\}$ and $\text{Lim}^{\uparrow_2(L)} L = \{s_{21}(L), \dots, s_{2l}(L)\}$. This means, the $s_{ab}(L)$ are the limit points of L , where $a = 1, 2$ stands for the two boundary vertices of L , ordered according to the chosen orientation.

Now take

$$M = \bigcup_L I_L / \sim',$$

where $\sim'$ is defined as follows: If $s \in \text{Lim}^{\uparrow_i(L)} L \cap \text{Lim}^{\uparrow_j(L')} L'$ for one (and then a unique) choice $i, j \in \{1, 2\}$ and $s = s_{ia}(L) = s_{jb}(L')$ then

$$I_L \ni \left(i-1, \frac{a-x}{k}\right) \sim' \left(j-1, \frac{b-x}{l}\right) \in I_{L'}$$

for $x \in (0, 1)$. This means, that the intervals in I_L resp $I_{L'}$ corresponding to s are identified.

The so defined topological space M can easily be made to a differentiable manifold, because after the choice of σ , the edges $\{L, L'\} = \kappa_\sigma(s)$ are unique and therefore a small neighbourhood of every point of M is topologically an open set in $\mathbb{R}^2$. The differentiability of the transition maps is just a formal calculation. The foliation $\mathcal{F}$ is given by $x = \text{const}$ if $(x, y) \in I_L$. Since the coordinates of the I_L can differ at most in the sign, there is a global one-form ω , which is closed and can locally be written

$$\omega = \sin(2\pi x) \, dx$$

Hence, ω defines the foliation $\mathcal{F}$ even in the zero locus of ω . $\square$

Figure 10:

In Fig. 10 we illustrated the rather technical construction of Theorem 5.12 for the graphical configurations of Fig. 4 resp. Fig. 3. In the second case, the right and left boundaries “a” are to be identified in converse direction. Hence the resulting manifold equals a Möbius surface without three certain rays. By a look at the manifold in Fig. 3(c) we see in particular, that the correspondence of graphical configurations and the pairs $(M, \mathcal{F})$ is not reversible.

5.3 The existence of Euler’s multiplier

Now we arrive at the main result of this paragraph which is an equivalent criterion on the graphical configuration $\delta(\mathcal{F})$ for the local or the global existence, respectively, of Euler’s multiplier.

Definition 5.13 (Eulerian configuration) Let $\mathcal{F}$ be a graphical C^r codim-1-foliation on M , $\delta(\mathcal{F}) = (\Gamma, (\gamma_\sigma)_\sigma)$ the graphical configuration of $\mathcal{F}$ with respect to the construction in 5.3, 5.5.

- (a) The configuration $\delta(\mathcal{F})$ is called *locally eulerian* if and only if $E = \emptyset$ and for each $\sigma \in \mathcal{V}\Gamma$ the corresponding micrograph γ_σ is bipartite (cf. Definitions 5.2, 5.10).
- (b) The configuration $\delta(\mathcal{F})$ is called *globally eulerian* if and only if the following three conditions hold:
 - (i) $\delta(\mathcal{F})$ is locally eulerian.
 - (ii) The bipartitions $\mathcal{V}_{\gamma_\sigma} = \mathcal{V}_{+\gamma_\sigma} \cup \mathcal{V}_{-\gamma_\sigma}$ of $\sigma \in \mathcal{V}\Gamma$ can be chosen such that, using the notation of 5.5 and 5.10, for $\sigma, \sigma' \in \mathcal{V}\Gamma$

$$\mathcal{E}\Gamma^\sigma \cap \mathcal{E}\Gamma^{\sigma'} = (\mathcal{V}_{+\gamma_\sigma} \cap \mathcal{V}_{-\gamma_{\sigma'}}) \cup (\mathcal{V}_{-\gamma_\sigma} \cap \mathcal{V}_{+\gamma_{\sigma'}}).$$

- (iii) There are no cycles $\sigma_1 L_1 \sigma_2 L_2 \sigma_3 \dots \sigma_N L_N \sigma_1$ with $L_i \in \mathcal{V}_{+\gamma_{\sigma_i}}$ for all $i = 1, \dots, N$ or $L_i \in \mathcal{V}_{-\gamma_{\sigma_i}}$ for all $i = 1, \dots, N$, where $N \in \mathbb{N}$.

At this occasion, we want to point out that Definition 5.13 has nothing to do with the usual definition of an *eulerian graph* in literature.

Remark 5.14 Obviously, the definition of a global eulerian configuration in Definition 5.13 (b) is equivalent to the following:

The configuration $\delta(\mathcal{F})$ is *globally eulerian* if and only if there is an orientation

$$\uparrow : \mathcal{E}\Gamma \rightarrow \mathcal{V}\Gamma \times \mathcal{V}\Gamma, \quad L \mapsto (\uparrow_1(L), \uparrow_2(L))$$

of Γ (cf. Def. 5.9) such that the following three conditions hold:

- (i) $E = \emptyset$.
- (ii) For each $\sigma \in \mathcal{V}\Gamma$ the micrograph γ_σ is bipartite such that, using the notation of Definition 5.10,

$$\mathcal{V}_{+\gamma_\sigma} = \{L \in \mathcal{V}_{\gamma_\sigma} \mid \uparrow_1(L) = \sigma\}, \quad \mathcal{V}_{-\gamma_\sigma} = \{L \in \mathcal{V}_{\gamma_\sigma} \mid \uparrow_2(L) = \sigma\}.$$

- (iii) The orientation $\uparrow$ induces a well-defined partial ordering “ $\leq$ ” on $\mathcal{V}\Gamma$ by

$$\begin{aligned} \sigma < \sigma' : \iff \exists N \in \mathbb{N}, \tau_1, \dots, \tau_N \in \mathcal{V}\Gamma, L_1, \dots, L_{N-1} \in \mathcal{E}\Gamma : \\ \tau_1 = \sigma, \tau_N = \sigma', \uparrow(L_j) = (\tau_j, \tau_{j+1}), j = 1, \dots, N-1, \end{aligned}$$

where $\sigma < \sigma'$ means $\sigma \leq \sigma'$ but $\sigma \neq \sigma'$.

Examples of locally eulerian or globally eulerian configurations are illustrated in Fig. 5.

In order to formulate our criterion for semiglobal existence of Euler's multiplier, we need some technical preparations:

Definition 5.15 A curve $\alpha : [a, b] \rightarrow M$ of class C^r is called *transversal*, if the mapping $\pi \circ \alpha : [a, b] \rightarrow M/\mathcal{F}$ is injective and

$$\forall t \in [a, b] : \quad \frac{d}{dt}(\pi \circ \alpha)(t) \neq 0.$$

Remark 5.16 Let $U \subset G = (M/\mathcal{F})/\sim$ an open set and $p : M/\mathcal{F} \rightarrow G$ the canonical projection (cf. Def. 4.3(a)). Then $\tilde{U} := \pi^{-1}(p^{-1}(U))$ is a saturated set in M satisfying

$$F \in \mathcal{F}, F \cap \tilde{U} \neq \emptyset \Rightarrow \bigcup_{F' \in [F]_{\sim}} F' \subset \tilde{U},$$

i.e. if $F \cap \tilde{U} \neq \emptyset$ for any leaf F then $\tilde{U}$ is a common saturated neighbourhood of all leaves $F' \in \mathcal{F}$ with $F' \in [F]_{\sim}$ according to Definition 4.3(a) (b).

Lemma 5.17 *Let $r \geq 1$ and $\mathcal{F}$ be a graphical C^r codim-1-foliation. Then the following conditions are equivalent:*

- (a) $\delta(\mathcal{F})$ is locally eulerian.
- (b) For each $x \in M$ there is some neighbourhood $U \subset G$ of $p(\pi(x))$, such that there is $f \in C^r(\tilde{U}, \mathbb{R})$ with $df(x) \neq 0$ in $\tilde{U}$ and $\mathcal{F}|_{\tilde{U}} = \mathcal{F}(df)$, where $\tilde{U} := \pi^{-1}(p^{-1}(U))$.

Condition (b) means the semiglobal existence of f .

Proof: Let (a) be satisfied. The transverse orientability of $\mathcal{F}$ and the existence of a piecewise C^r function f_0 without extrema like described are rather technical to prove, but plausible. So we omit this part. Furthermore it is clear that after any choice of a non-Hausdorff leaf F_0 the function f_0 can be chosen C^r around F_0 with $df_0 \neq 0$ on F_0 . Now C^r -regularity and transverse orientability of $\mathcal{F}$ imply that there is a saturated neighbourhood U_0 of F_0 and a function $\tilde{f} \in C^r_{\mathcal{F}}(M)$ such that $f_0|_{U_0} = \tilde{f}|_{U_0}$. For any $F_i \sim F_0$ holds automatically $d\tilde{f} \neq 0$ on F_i : Let T be a local transversal through $x \in F_0$ with injective projection to $M/\mathcal{F}$; this exists, since we assumed $E = \emptyset$. The function $x \in F_t(t \in T) \mapsto \frac{1}{d\tilde{f}(\frac{\partial}{\partial t})}$ would be in $C^{r-1}_{\mathcal{F}}(\text{sat}(T))$ and not be extendable beyond F_i , if $d\tilde{f}|_{F_i} = 0$. So for all $F_i \sim F$ there is a saturated neighbourhood $U_i \supset F_i$ such that $d\tilde{f} \neq 0$ on U_i . We set $U := \bigcup_{F_i \in [F]_{\sim}} U_i$ and $f := \tilde{f}|_U$.

In order to prove the other direction, (b) $\Rightarrow$ (a), the arguments are again technical, but straightforward. $\square$

Theorem 5.18 (Criterion for global existence) *Let $\mathcal{F}$ be a graphical C^r codim-1-foliation. Then the following conditions are equivalent:*

- (a) $\delta(\mathcal{F})$ is globally eulerian.
- (b) There is some function $f \in C^r(M, \mathbb{R})$ such that $df(x) \neq 0$ in M and $\mathcal{F} = \mathcal{F}(df)$.

Proof: (i) Suppose $\delta(\mathcal{F})$ to be globally eulerian. Let $\mathcal{R} := \mathcal{V}\Gamma$ be partially ordered according to 5.14 (i)(iii) and let $a : \mathcal{V}\Gamma \rightarrow \mathbb{Q}$ be any mapping satisfying

$$\sigma < \sigma' \implies a(\sigma) < a(\sigma')$$

Moreover, for each $\sigma \in \mathcal{V}\Gamma$ choose $\epsilon_\sigma \in (0, 1)$ with

$$(7) \quad \epsilon_\sigma < \frac{1}{3} \min \left\{ |a(\sigma') - a(\sigma)| \mid \sigma' \in \mathcal{V}\Gamma, \exists L \in \mathcal{E}\Gamma : \kappa(L) = \{\sigma, \sigma'\} \right\}.$$

Let $\tilde{U}_\sigma$ be an appropriate neighbourhood of σ , $x \in s \in \mathcal{E}\gamma_\sigma$ and $f_\sigma \in C^r(\tilde{U}_\sigma, \mathbb{R})$ the corresponding mapping as in condition (b) of Lemma 5.17. Without any restriction we may assume $f_\sigma(x) \in [-\epsilon_\sigma, +\epsilon_\sigma]$ for each $x \in \tilde{U}_\sigma$ and $\tilde{U}_\sigma \cap \tilde{U}_{\sigma'} = \emptyset$ for $\sigma' \in \mathcal{V}\Gamma \setminus \{\sigma\}$. Now define

$$\tilde{f} : \bigcup_{\sigma \in \mathcal{V}\Gamma} \tilde{U}_\sigma \rightarrow \mathbb{R}, \quad \tilde{f}(x) := a(\sigma) + f_\sigma(x) \quad \text{for } x \in \tilde{U}_\sigma.$$

Let $L \in \mathcal{E}\Gamma$, $\kappa(L) = \{\sigma, \sigma'\}$, $L \in \mathcal{V}_+\gamma_\sigma \cap \mathcal{V}_-\gamma_{\sigma'}$. Thus, we have $a(\sigma) < a(\sigma')$ and, using condition (7),

$$\forall x \in \tilde{U}_\sigma, x' \in \tilde{U}_{\sigma'} : \quad \tilde{f}(x) < \tilde{f}(x').$$

Moreover, let $u \in C^r([0, 1], M)$ be some transversal curve according to 5.15 such that $\pi \circ u \in \mathbf{W}$ and $L = [\pi \circ u]_\sim$ (For the definition of $\mathbf{W}$ see Construction 5.3). For $x \in M$ with $x \in L$ according to (5) we define

$$f(x) := \phi\left((\pi \circ u)^{-1}(\pi(x))\right).$$

for a suitably chosen strictly increasing function $\phi \in C^r([0, 1])$. After an appropriate reparametrization of u , we can achieve $f(x) = \tilde{f}_\sigma(x)$ for $x \in \tilde{U}_\sigma$, $\sigma \in \mathcal{V}\Gamma$. Then f has the desired properties.

(ii) Now suppose condition (b) to be fulfilled. From Lemma 5.17 we know that Γ is locally eulerian. An ordering on $\mathcal{V}\Gamma$ and therefore an orientation $\uparrow$ of Γ according to Remark 5.14 (iii) is induced by f , given by

$$\sigma < \sigma' \quad \text{if} \quad f(\xi) < f(\xi'),$$

where $\sigma, \sigma' \in \mathcal{V}\Gamma$, $\xi, \xi' \in M$ with $p(\pi(\xi)) = \sigma$, $p(\pi(\xi')) = \sigma'$ (cf. Def. 4.3(a))

Furthermore, to see the bipartition of $\mathcal{V}\gamma_\sigma$, define $\mathcal{V}_+\gamma_\sigma$, $\mathcal{V}_-\gamma_\sigma$ as in Remark 5.14 (ii). $\square$

5.4 The case $b_1(M) = 0$

If $\mathcal{F}$ is a graphical foliation, then denote $\delta(\mathcal{F}) = (\Gamma, (\gamma_\sigma)_\sigma)$ the graphical configuration. Like above, we denote $\Gamma = (\mathcal{V}\Gamma, \mathcal{E}\Gamma)$ and similar for other graphs. Let us define the main graph $\mu = \mu(\mathcal{F})$ by

$$\mathcal{V}\mu := \bigcup_{\sigma \in \mathcal{V}\Gamma} \mathcal{V}\gamma_\sigma, \quad \mathcal{E}\mu := \mathcal{E}\Gamma \cup \bigcup_{\sigma \in \mathcal{V}\Gamma} \mathcal{E}\gamma_\sigma$$

and the corresponding boundary mapping

$$\kappa_\mu : \mathcal{E}\mu \rightarrow S^2\mathcal{V}\mu, \quad \kappa_\mu(\Lambda) := \begin{cases} \kappa_\sigma(\Lambda), & \text{if } \Lambda \in \mathcal{E}\gamma_\sigma \\ \{\Lambda_\sigma, \Lambda_{\sigma'}\}, & \text{if } \Lambda \in \mathcal{E}\Gamma \end{cases},$$

where in the second case $\{\sigma, \sigma'\} = \kappa_\Gamma(\Lambda) = \kappa(\Lambda)$ (cf. (4) in Construction 5.3) and Λ_σ denotes Λ as element of $\mathcal{V}\gamma_\sigma$, correspondingly for σ' .

This means, that μ is the graph we obtain, if we replace the vertices of Γ with their corresponding micrographs.

Let μ and Γ also denote the topological space associated to the graph μ resp. Γ . Then it is clear that there is a continuous map

$$c : \mu \longrightarrow \Gamma,$$

which contracts the γ_σ to the point σ and is an isomorphism outside the micrographs. Moreover, there is a continuous map

$$\tilde{c} : \mu \longrightarrow M/\mathcal{F},$$

which identifies the edges of γ_σ with the corresponding non-Hausdorff leaves in $M/\mathcal{F}$, and is an isomorphism outside the micrographs. This map satisfies $c = p \circ \tilde{c}$. The fibres $c^{-1}(g)$ of $\tilde{c}$ are homeomorphic to intervals, hence they are simply connected. Outside of the micrographs $\tilde{c}$ is an isomorphism and $M/\mathcal{F}$ is a one-dimensional manifold outside the non-Hausdorff points. As usual, we denote $b_1(Y) := rkH^1(Y, \mathbb{Z})$ for a topological space Y .

By standard topological methods we obtain $H^1(M/\mathcal{F}, \mathbb{Z}) \cong H^1(\mu, \mathbb{Z})$. Applying this we arrive at

Lemma 5.19 *If $\delta(\mathcal{F})$ is the graphical configuration of a foliation, then*

- (a) $b_1(M/\mathcal{F}) \leq b_1(M)$,
- (b) $b_1(\Gamma) + \sum_{\sigma \in \mathcal{V}\Gamma} b_1(\gamma_\sigma) = b_1(M/\mathcal{F})$,
- (c) Γ and all γ_σ are simply connected, if $b_1(M/\mathcal{F}) = 0$.

Now we can derive the global existence theorem for manifolds with $b_1(M) = 0$:

Theorem 5.20 *Let M be a manifold with $b_1(M) = 0$ and $\mathcal{F}$ a graphical C^r codim-1-foliation. Then there is a C^r function $f : M \longrightarrow \mathbb{R}$ with $df(x) \neq 0$ everywhere and $\mathcal{F} = \mathcal{F}(df)$.*

Proof: By Lemma 5.19 we know, that Γ and all γ_σ are simply connected, so they contain no cycle. Since a graph is bipartite if and only if every cycle has an even number of edges, we conclude, that all γ_σ are bipartite, hence $\delta(\mathcal{F})$ is locally eulorian. Now let us define an orientation of Γ inductively: choose any $\sigma \in \mathcal{V}\Gamma$ and a bipartition

$$\mathcal{V}\gamma_\sigma = \mathcal{V}_+\gamma_\sigma \cup \mathcal{V}_-\gamma_\sigma$$

For any $L \in \mathcal{E}\Gamma^\sigma$ choose the orientation $\uparrow(L)$ and the bipartition of the neighboured micrographs so that

$$\begin{aligned} \uparrow_1(L) &= \sigma \wedge L \in \mathcal{V}_-\gamma_{\uparrow_2(L)}, & \text{if } L \in \mathcal{V}_+\gamma_\sigma, \\ \uparrow_2(L) &= \sigma \wedge L \in \mathcal{V}_+\gamma_{\uparrow_1(L)}, & \text{if } L \in \mathcal{V}_-\gamma_\sigma. \end{aligned}$$

Now we are looking at the neighbouring micrographs and repeat this procedure. This will give a complete system of orientation of Γ and bipartitions of the γ_σ , because Γ is connected. We have to show that there are no inconsistencies. But if there are any, say at $\gamma_{\sigma'}$, there would be two different paths

$$\sigma L_1 \sigma_1 \dots \sigma_{k-1} L_k \sigma' \quad \text{resp.} \quad \sigma L_k \sigma_k \dots \sigma_{l-1} L_l \sigma'.$$

Hence the path

$$\sigma L_1 \sigma_1 \dots \sigma_{k-1} L_k \sigma' L_l \sigma_{l-1} \dots \sigma_k L_k \sigma$$

would contain a circuit, what contradicts $b_1(\Gamma) = 0$.

In particular, there can be no oriented circuits, so we conclude that $\delta(\mathcal{F})$ is globally eulerian. By Theorem 5.18 the proof is finished. $\square$

6 Applications

6.1 Tools

This section is intended to provide tools for the investigation of foliations. In particular, there is some simplification for the test of the graphicalness of a foliation.

6.1.1 Closedness of leaves

If we assume a leaf F of a C^∞ codim-1-foliation $\mathcal{F}$ on a manifold M to be not closed (topological), then F as a point in $M/\mathcal{F}$ is a non-Hausdorff point. This we see by considering $\overline{F}$. It is easy to see that $\overline{F}$ is saturated, hence there exists a leaf $F' \subset \overline{F} \setminus F$. Clearly, F' and F cannot be separated by open neighbourhoods. Hence Hausdorff leaves are closed.

If we want to verify the graphicalness of a foliation it turns out that this gets much simpler, if on M the Jordan Brouwer Separation Theorem holds for closed leaves, that means:

Definition 6.1 A manifold M is called *foliated Jordan Brouwer separable* (fJBS), if for any C^∞ codim-1-foliation $\mathcal{F}$ and closed leaf $F \in \mathcal{F}$ holds: $M \setminus F$ has at least two connected components.

Lemma 6.2 Any manifold M with $H_1(M, \mathbb{Z}) = 0$ is fJBS.

Proof: For any manifold Z we denote by $\mathcal{A}_Z$ the sheaf of C^∞ functions on Z . Let F be a closed leaf of a foliation $\mathcal{F}$ and $U(F)$ a small tubular neighbourhood. The condition $H_1(M, \mathbb{Z})$ implies that the part of the Mayer-Vietoris sequence

$$0 \longrightarrow H_0(U(F) \setminus F, \mathbb{Z}) \longrightarrow H_0(M \setminus F, \mathbb{Z}) \oplus H_0(F, \mathbb{Z}) \longrightarrow H_0(M, \mathbb{Z}) \longrightarrow 0$$

is exact. Since $H_0(U(F) \setminus F, \mathbb{Z}) = H_0(|N_F| \setminus F, \mathbb{Z})$, if $|N_F|$ denotes the total space of the normal bundle of F , it is enough to show $N_F \cong \mathcal{A}_F$: Then $|N_F| = F \times \mathbb{R}$, hence $|N_F| \setminus F = F \times (\mathbb{R} \setminus \{0\})$.

The crucial point is now that N_F extends to the line bundle $N_{\mathcal{F}}$ on M . Real line bundles are parametrised by $H^1(M, \mathbb{Z}_2)$, however. By the universal coefficient lemma this group vanishes, so any line bundle on M is trivial, in particular $N_{\mathcal{F}} \cong \mathcal{A}_M$. This again implies $N_F \cong \mathcal{A}_F$.

Note that we even proved that $M \setminus F$ has exactly two components. $\square$

Lemma 6.3 Let M be fJBS manifold and $\mathcal{F}$ a codim-1-foliation on M . Then the set

$$C := \{F \in M/\mathcal{F} \mid F \text{ is a closed leaf}\}$$

is closed.

The proof is straightforward and hence left to the reader.

Note that a leaf $F \subset M$ is closed if and only if $F \in M/\mathcal{F}$ is a closed point.

The lemma implies immediately:

Corollary 6.4 *Let M be a fJBS manifold. Then a regular C^r codim-1-foliation $\mathcal{F}$ is graphical if and only if $p(S)$ is a discrete set, and for every $g \in G$ the fibre $p^{-1}(g)$ is a finite set, where S is like in Definition 4.3(a) the set of non-Hausdorff points.*

Proof: By the discreteness assumption, $G \setminus p(S)$ is open and dense, hence $H := M/\mathcal{F} \setminus S$ is open, since p is continuous, and dense, since the fibres are finite. But H is the set of Hausdorff points, hence $H \subset C$. This means by Lemma 6.3 that $C = \overline{C} = M/\mathcal{F}$, hence all leaves are closed. $\square$

6.1.2 Characterization of infinitely near leaves

Here we give criteria for constructing the graphical configuration directly from the one-form. We suppose M to be Riemannian. Then we have the notion of the normal bundle $N_{\mathcal{F}}$ to $\mathcal{F}$, defined by

$$N_{\mathcal{F},x} := (T_x F_x)^\perp,$$

where F_x is the leaf containing x . A normal curve $b : [0, 1] \rightarrow M$ then is a curve with $\dot{b}(t) \in N_{\mathcal{F},b(t)}$ for all $t \in [0, 1]$, i.e. an integral curve of the normal bundle.

Figure 11: A normal path

Let us define a *normal path* β connecting $x \in F$ and $x' \in F'$ as the sum $\nu + b + \nu'$, where $\nu, \nu' : I \rightarrow M$ are paths whose image is contained in the curve normal to $\mathcal{F}$ meeting x resp x' and $\nu(0) = x, \nu'(1) = x'$, and b is a path whose image is contained in a leaf $\tilde{F}$ and $\nu(1) = b(0), b(1) = \nu'(0)$

Lemma 6.5 *Let ω be an integrable one-form without zeroes on the Riemannian manifold (M, g) and $\mathcal{F} = \mathcal{F}(\omega)$ the induced foliation. Then the classes of any two leaves F and F' are infinitely near in $M/\mathcal{F}$ if and only if for some (and hence all) $x \in F, x' \in F'$ and all $\varepsilon > 0$ exists a piecewise continuous differentiable normal path $\beta : [0; 1] \rightarrow M$ with $\beta(0) = x, \beta(1) = x'$ and*

$$\int_{\beta} |\omega| := \int_0^1 |\beta^*(\omega)(\frac{d}{ds})| ds < \varepsilon$$

Proof: $\Rightarrow$: If F, F' are infinitely near, then by definition, any saturated neighbourhoods

$$U_{\delta}(F) := \left\{ \tilde{F} \in M/\mathcal{F} \left| \inf_{x \in F, \tilde{x} \in \tilde{F}} (dist_g(x, \tilde{x})) < \delta \right. \right\}$$

and, analogously defined, $U_{\delta}(F')$ satisfy

$$U_{\delta}(F) \cap U_{\delta}(F') \neq \emptyset$$

So, if $B_\delta(x)$ is the geodesic ball of radius δ around x and $l_x : [0; 1] \longrightarrow B_\delta(x)$ is a curve normal to $\mathcal{F}$ with $l_x(0) = x$, and analogously for $l_{x'}$, such that there is a leaf $\tilde{F}$ with $l_x(1) \in \tilde{F} \ni l_{x'}(1)$, then let $\alpha : [0; 1] \longrightarrow \tilde{F}$ be a path from $l_x(1)$ to $l_{x'}(1)$ and finally

$$\beta := l_x + \alpha + l_{x'}$$

Clearly, β is a normal path. If we choose δ sufficiently small, we can achieve

$$(8) \quad \int_\beta |\omega| < \varepsilon.$$

' $\Leftarrow$ ': Let U and U' be small saturated neighbourhoods of F resp. F' . It is an easy argument, that for sufficiently small $\varepsilon > 0$, the normal paths β_ε are contained in $U \cap U'$. In particular, $U \cap U' \neq \emptyset$. □

Lemma 6.6 *Let ω be an integrable one-form without zeroes on the complete Riemannian manifold M and $\mathcal{F} = \mathcal{F}(\omega)$ the induced foliation. F and F' are infinitely near in $M/\mathcal{F}$ if and only if for any saturated neighbourhoods $U(F), U'(F')$ there is a by arc length parametrized curve $\nu : \mathbb{R}^+ \longrightarrow M$ which is normal to the foliation, with $\nu(\mathbb{R}^+) \cap F = \emptyset$, $\nu(\mathbb{R}^+) \cap F' = \emptyset$, but $\nu(\mathbb{R}^+) \cap U(F) \cap U'(F') \neq \emptyset$.*

Proof: ' $\Leftarrow$ ': If $\nu(\mathbb{R}^+) \cap U(F) \cap U'(F') \neq \emptyset$ for saturated neighbourhoods $U(F), U'(F')$, then $U(F) \cap U'(F') \neq \emptyset$, hence F and F' are infinitely near.

' $\Rightarrow$ ': For any neighbourhoods $U(F), U'(F')$ there is an $\varepsilon > 0$ such that

$$U \cap U' \subset U(F) \cap U'(F'),$$

with saturated sets $U := \pi^{-1} \circ \pi \circ \nu_\varepsilon([0, 1])$, $U' := \pi^{-1} \circ \pi \circ \nu'_\varepsilon([0, 1])$ containing F resp. F' where $\beta_\varepsilon = \nu_\varepsilon + b + \nu'_\varepsilon$ denotes a normal path satisfying (8) like in the proof of Lemma 6.5. Furthermore fix a leaf $\tilde{F} \subset U \cap U'$. Now look at the continuous map induced by the transport along the normal curves to $\mathcal{F}$

$$n : H \longrightarrow \tilde{F},$$

where H is the locus of points $p \in F \cup F'$ such that the normal curve through p meets $\tilde{F}$. By construction, $H \cap F \neq \emptyset$, $H \cap F' \neq \emptyset$, so H has at least two connected components. Since through a point passes exactly one normal curve, n is injective, hence $n(H)$ has at least two connected components. Thus $n(H) \neq \tilde{F}$. Now take a point $x \in \tilde{F} \setminus n(H)$ and look at the normal curve $\nu : \mathbb{R}^+ \longrightarrow M$ with $\nu(0) = x$. By completeness of M it can be achieved, that ν is parametrized by arc length with domain $\mathbb{R}^+$. This curve satisfies every condition of the lemma. □

6.2 Special cases

In this section we present special cases, in which the decision of the existence of an Eulerian multiplier is easier than in other cases. These examples are compact leaves of the foliation and a cylinder form of the manifold.

Figure 12: Examples for the curve ν in Lemma 6.6

6.2.1 The case of compact leaves

Let us discuss the case that the leaves are compact. It will turn out that under compactness of the leaves $\text{Hol}(F) = 1$ is equivalent to the existence of an Eulerian multiplier.

Theorem 6.7 *Let M be a non-compact C^r manifold and $\mathcal{F}$ a codimension one C^r foliation, such that all leaves F are compact and $\text{Hol}(F) = 1$. Then there is a C^r function $f : M \rightarrow \mathbb{R}$ satisfying $\mathcal{F} = \mathcal{F}(df)$ and $df(x) \neq 0$ in M .*

Proof: By [CN, Ch. IV, Lemma 6], for any leaf F there is a saturated neighbourhood $U(F)$ together with a commutative diagram

$$\begin{array}{ccc} U(F) & \xrightarrow{h} & I \times F \\ \downarrow \pi & & \downarrow pr \\ V & \xrightarrow{i_V} & I \end{array}$$

where V is an open set in $M/\mathcal{F}$, I is an interval in $\mathbb{R}$, h is a C^r diffeomorphism and i_V a homeomorphism. This suggests a natural Hausdorff manifold structure on $M/\mathcal{F}$. By the non-compactness of M we deduce that $M/\mathcal{F}$ is not compact and hence diffeomorphic to $\mathbb{R}$. Thus the projection is the desired function f . $\square$

This theorem allows a stronger result, if $\pi_1(M)$ is finite, much similar to Corollary 5.20. Indeed, the proof of Theorem 6.7 used in the following shows with some extra arguments presented below, that $\mathcal{F}$ is a graphical foliation, if $\pi_1(M)$ is finite and all leaves are compact:

Corollary 6.8 *Let M be a non-compact Riemannian manifold with finite fundamental group $\pi_1(M)$. If $\mathcal{F}$ is a C^r codimension one foliation with only compact leaves, then there is a C^r function $f : M \rightarrow \mathbb{R}$ with $df(x) \neq 0$ for all $x \in M$ such that $\mathcal{F} = \mathcal{F}(df)$.*

Proof: (i) As a first case, let us assume $\pi_1(M) = 0$.

By Lemma 5.8 we know that $\text{Hol}(F) \in \{1, \mathbb{Z}_2\}$ for all leaves F . Now we can follow the proof of the Corollary in [CN, Ch. IV, §5] to see that $\text{Hol}(F) = 1$ if the normal bundle $N_{\mathcal{F}}$ to $\mathcal{F}$ is orientable. But since $\pi_1(M) = 0$ every vector bundle over M is orientable; in particular, so is $N_{\mathcal{F}}$. So we now can apply Theorem 6.7 to complete the proof.

(ii) If $|\pi_1(M)| = d$ is finite, we look at the universal cover $\tilde{M} \xrightarrow{u} M$, what is a $d : 1$ -cover. The foliation $\tilde{\mathcal{F}} := u^*\mathcal{F}$ then has also only compact leaves, since for a

leaf $\tilde{F} \in \tilde{\mathcal{F}}$ the map $u|_{\tilde{F}} : \tilde{F} \longrightarrow F$, with $F \in \mathcal{F}$ is a finite cover also (maybe of lower order). So we can apply the first part for $(\tilde{M}, \tilde{\mathcal{F}})$ and see that $\tilde{\mathcal{F}}$ is graphical. This implies immediately that $\mathcal{F}$ is of finite type. In order to see that $\mathcal{F}$ is regularly C^r , by definition we may assume that $\mathcal{F}$ is transversely orientable, hence given by an integrable one-form ω . By the first part, $u^*\omega = \tilde{f}d\tilde{g}$ with nonvanishing $\tilde{f}$; so we may assume $\tilde{f} > 0$. Applying standard covering theory yields $\omega = fdg$ with

$$f \circ u = \frac{1}{d} \left(\sum_{\phi \in \text{Deck}(\tilde{M}, M)} \frac{1}{\tilde{f} \circ \phi} \right)^{-1}, \quad g \circ u = \frac{1}{d} \sum_{\phi \in \text{Deck}(\tilde{M}, M)} \tilde{g} \circ \phi.$$

In particular, $\mathcal{F}$ is given by a closed one-form, so it is regularly C^r . Now we know that $\mathcal{F}$ is graphical. The finiteness of $\pi_1(M)$ implies $b_1(M) = 0$. Now we apply Theorem 5.20 and thereby proved the claim. $\square$

Example 6.9 If we take $M = \mathbb{R}^n \setminus \{0\}$, ω a one-form on M such that all leaves of $\mathcal{F}(\omega)$ are diffeomorphic to S^{n-1} , then the existence of an Eulerian multiplier is given by Corollary 6.8, if $n \geq 3$. For $n = 2$ the statement can be proved by elementary means. $\triangle$

6.2.2 The case of an infinite cylinder

Finally, we mention an obvious result.

Theorem 6.10 *Let $D \subset \mathbb{R}^n$ be a simply connected domain, $M := D \times \mathbb{R}$. Moreover, let $v = (v^1, \dots, v^{n+1}) \in C^r(M, \mathbb{R}^{n+1})$ such that $v^{n+1}(x) \neq 0$ for all $x \in M$ and $|\frac{v^i}{v^{n+1}}| \leq C$ for all i and some constant C . Let $\omega =: \sum_{k=1}^{n+1} v^k dx_k$ be integrable. There are functions $f \in C^r(M, \mathbb{R})$ and $\lambda \in C^{r-1}(M, \mathbb{R})$ satisfying $\lambda(x) \neq 0$ in M and*

$$df = \lambda\omega.$$

Proof: The assumptions imply that for every leaf the projection $F \longrightarrow D$ is onto and locally an isomorphism (in the abstract manifold structure of F). Since $\pi_1(D) = 0$, the projection has to be a global isomorphism. In particular, $M/\mathcal{F} \cong \mathbb{R}$ and the claim follows. $\square$

Remark: Note that, of course, the property $\omega \wedge d\omega = 0$ and the existence of Euler's multiplier are invariant under C^r -diffeomorphisms $\Phi : M \rightarrow M'$, $r \geq 2$. Thus, the result of this theorem still holds if M and the conditions are “deformed” consistently.
